### Ensemble Methods, Random Forests and Boosting

Data Science Dojo

# Agenda

- Overview and rationale
- Why ensemble?
  - Binomial Distribution
- Ensemble models
  - Bagging
  - Random Forests
  - Boosting
  - AdaBoost

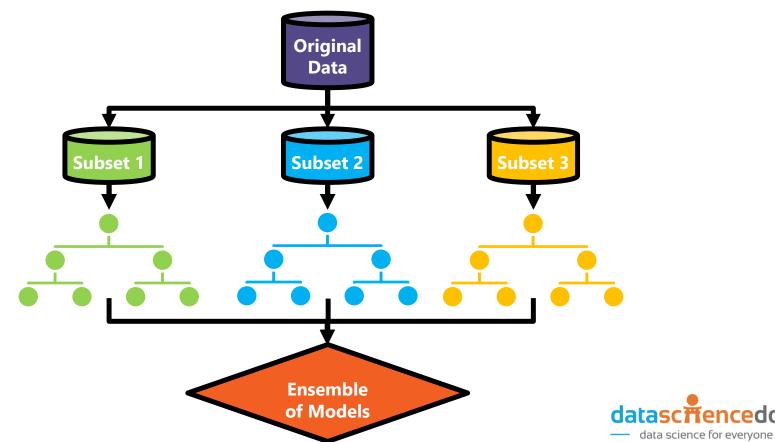

### **Ensemble Methods**

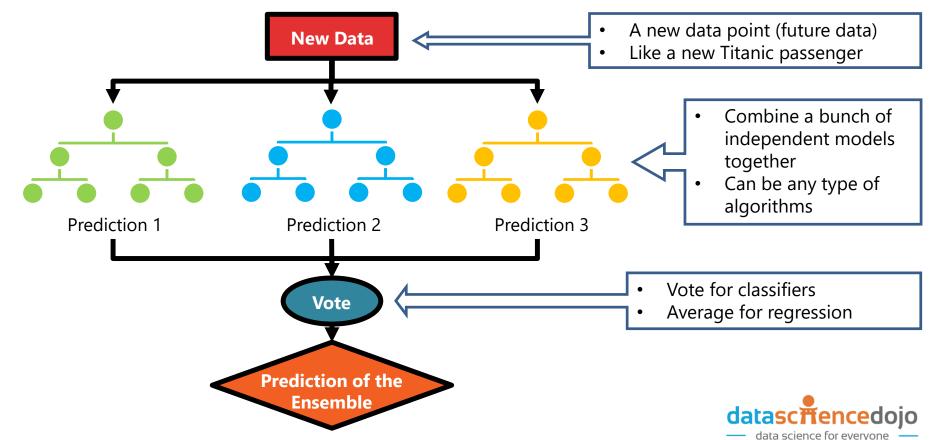

- Improve model performance by combining multiple models
- Can be used for both classification and regression

#### **Ensemble of Decision Tree Models**

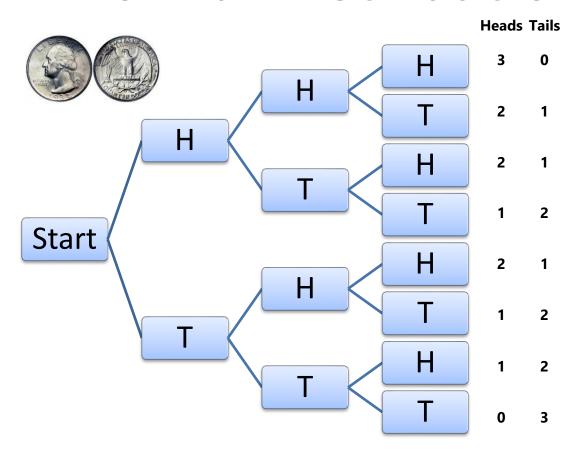

#### **Ensemble of Decision Tree Models**

#### BINOMIAL DISTRIBUTION

### **Binomial Distribution**

#### Consider...

- Flipping a coin 3 times in a row
- Each coin flip is considered independent
- A fair coin has a 50% rate of heads and tails

#### Properties of a binomial distribution:

- Well studied statistical property
- You cannot tell how each individual coin toss session will behave or their individual outcomes (such as HHH or HTH)
- However you can tell and predict the behavior of the aggregations of many coin toss sessions

### **Binomial Distribution**

$$f(k; n, p) = P(X = k) = {n \choose k} p^k (1-p)^{n-k}$$

#### **Exercises**

#### Supplementary Material

Ex 1: You roll a die 4 times. What is the probability of rolling a "5" at least 3 times?

Ex 2: A test consists of ten multiple choice questions with five choices for each question. What is the probability of getting at least 6 questions correct?

# **Applications**

- Number of life insurance holders who will claim in a given period
- Number of loan holders who will default in a certain period
- Number of false starts of a car in n attempts
- Number of faulty items in n samples from a production line
- AND Ensemble Methods

### Why Does It Work?

- Suppose there are 25 base classifiers
  - Each classifier has error rate,  $\varepsilon = 0.35$
  - Assume classifiers are independent
  - Probability that the ensemble classifier makes a wrong prediction:

$$\sum_{i=13}^{25} {25 \choose i} \varepsilon^i (1-\varepsilon)^{25-i} = 0.06$$

### **Examples of Ensemble Methods**

### Bagging

All classifiers are created equal

### Boosting

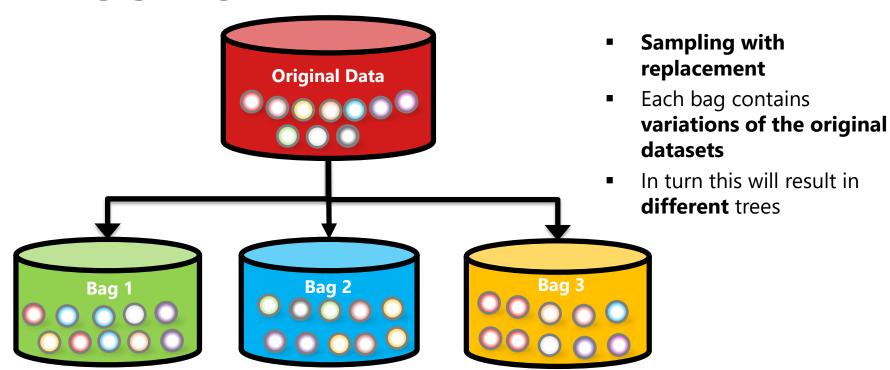

Not all classifiers are created equal

### **BAGGING**

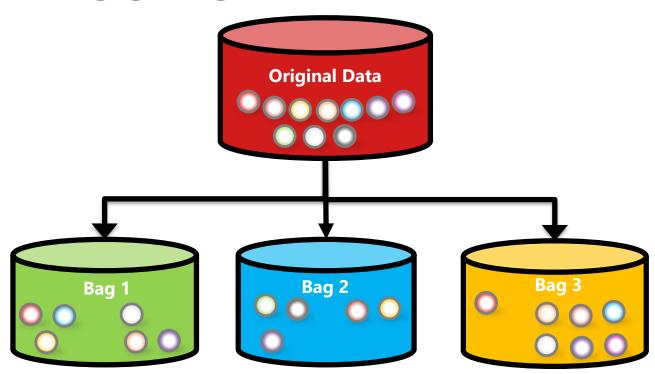

### Bagging

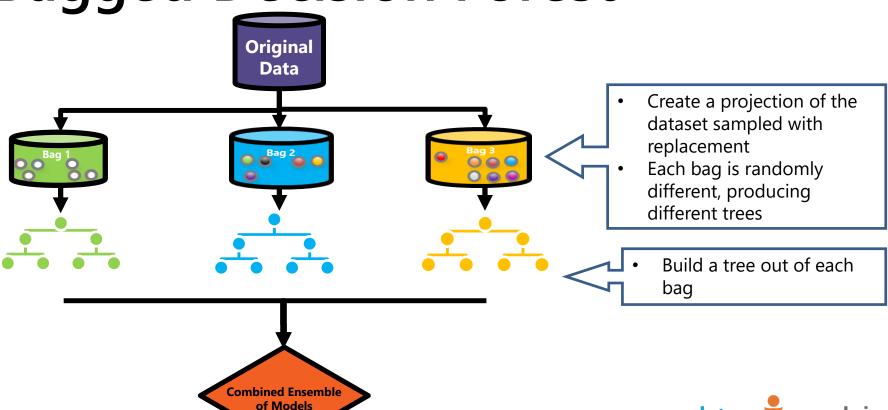

# Bagging

### **Bagged Decision Forest**

# Bagging

Sampling with replacement

Original Data	1	2	3	4	5	6	7	8	9	10
Bagging (Round 1)	7	8	10	8	2	5	10	10	5	9
Bagging (Round 2)	1	4	9	1	2	3	2	7	3	2
Bagging (Round 3)	1	8	5	10	5	5	9	6	3	7

- Build classifier on each bootstrap sample
- For a training data of size n, each sample has probability [1 - (1 – 1/n)<sup>n</sup>] of being selected
- If n is large, this approximates to 1-1/e ~ 0.632

# Bagging

- Reduces variance in estimate
- Prevents overfitting
- Robust to outliers

#### RANDOM FORESTS

### What Is A Random Forest?

- An ensemble classifier using many decision tree models
- Can be used for classification or regression
- Accuracy and variable importance information is built-in

#### **How Do Random Forests Work?**

- A different subset of the training data are selected (~2/3), with replacement, to train each tree
- Remaining training data (aka out-of-bag data or simply OOB) is used to estimate error and variable importance
- Class assignment is made by the number of votes from all of the trees, and for regression, the average of the results is used

### Which Features Are Used For Learning?

- A randomly selected subset of variables is used to split each node
- The number of variables used is decided by the user (mtry parameter in R)
- A smaller subset produces less correlation (lower error rate)

### Rules of Thumb

- Given:
  - N: Total number of training data points
  - **M:** Number of features in training data
  - m: Number of features randomly selected for training each node

- Sample the data with replacement N times for building the training data for each tree.
- m < < M</p>
- Classification: m = sqrt(M)
- Regression: m = M/3

## Learning a Forest

- Dividing training examples into T subsets improves generalization
  - Reduces memory requirements & training time
- Train each decision tree t on subset I<sub>t</sub>
  - Same decision tree learning as before
- Multi-core friendly (GPU implementation)

### Implementation Details

- How many features and thresholds to try?
  - Just one = "extremely randomized" [Geurts et al. 06]
  - Few → fast training, may under-fit, may be too deep
  - Many → slower training, may over-fit
- When to stop growing the tree?
  - Maximum depth
  - Minimum entropy gain
  - Delta class distribution
  - Pruning

### Random Forest: R Exercise

### **BOOSTING**

# Boosting

- An iterative procedure to adaptively change distribution of training data by focusing more on previously misclassified records
  - Initially, all N records are assigned equal weights
  - Unlike bagging, weights may change at the end of boosting round

# Boosting

- Records that are wrongly classified will have their weights increased
- Records that are classified correctly will have their weights decreased

Original Data	1	2	3	4	5	6	7	8	9	10
<b>Boosting (Round 1)</b>	7	3	2	8	7	9	4	10	6	3
<b>Boosting (Round 2)</b>	5	4	9	4	2	5	1	7	4	2
<b>Boosting (Round 3)</b>	4	4	8	10	4	5	4	6	3	4

- Example 4 is hard to classify
- Its weight is increased, therefore it is more likely to be chosen again in subsequent rounds

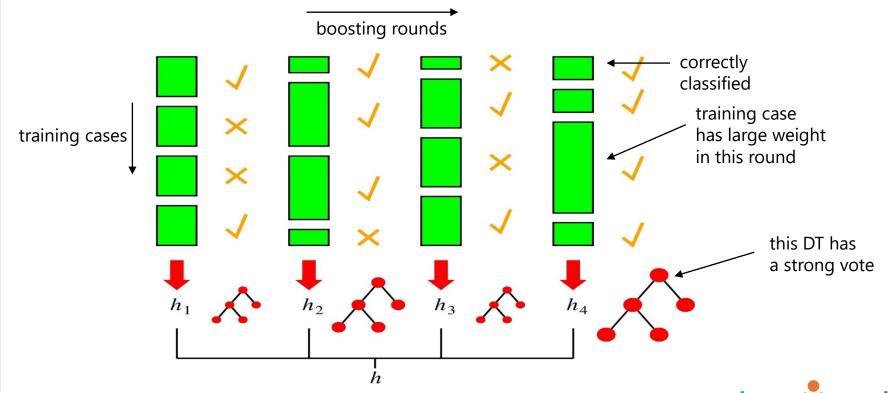

## **Boosting Intuition**

- We adaptively weight each data case.
- Data cases which are wrongly classified get high weight (the algorithm will focus on them).
- Each boosting round learns a new (simple) classifier on the weighed dataset.
- These classifiers are weighed to combine them into a single powerful classifier.
- Classifiers that obtain low training error rate have high weight.
- We stop by monitoring a hold out set.

# **Boosting in a Picture**

data science for everyone

### **ADABOOST**

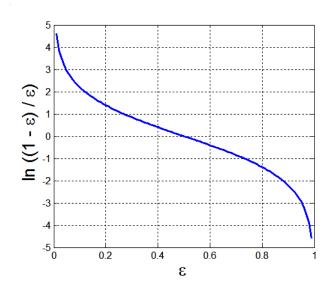

# AdaBoost (Adaptive Boosting)

- Base classifiers: C<sub>1</sub>, C<sub>2</sub>, ..., C<sub>T</sub>
- Error rate [Weighted loss function]:

$$\varepsilon_i = \frac{1}{N} \sum_{j=1}^{N} w_j \delta(C_i(x_j) \neq y_j)$$

Importance of a classifier:

$$\alpha_i = \frac{1}{2} \ln \left( \frac{1 - \varepsilon_i}{\varepsilon_i} \right)$$

### AdaBoost

Weight update:

$$w_i^{(j+1)} = \frac{w_i^{(j)}}{Z_j} \begin{cases} \exp^{-\alpha_j} & \text{if } C_j(x_i) = y_i \\ \exp^{\alpha_j} & \text{if } C_j(x_i) \neq y_i \end{cases}$$

where  $Z_i$  is the normalization factor

- If any intermediate rounds produce error rate higher than 50%, the weights are reverted back to 1/n and the resampling procedure is repeated.
- Classification:  $C * (x) = \underset{y}{\operatorname{arg max}} \sum_{j=1}^{T} \alpha_{j} \delta(C_{j}(x) = y)$

### **Common Pitfall**

A Random Forest and a Boosted Decision Tree are **not** the same

### QUESTIONS
